How to Perform Endoscopy During Exercise Without a Treadmill

Youssef Tamzali, DVM, PhD, DECEIM; Nicolas Serraud, DVM; Bruno Baup, DVM; and Louis-Marie Desmaizieres, DVM

Exercising endoscopy can be performed without a treadmill using specifically developed equipment that enables real-time visualization and recordings in natural exercising conditions. The more stable images obtained with this system also improve the quality of images obtained during treadmill endoscopy. Authors’ addresses: Equine Internal Medicine, Ecole Nationale Vétérinaire, 23 chemin des Capelles, 31076 Toulouse, France (Tamzali); and Clinique Vétérinaire Equine de la Brousse, 31330 Grenade, France (Serraud, Baup, Desmaizieres); e-mail: y.tamzali@envt.fr. © 2008 AAEP.

1. Introduction
Dynamic obstructions of the equine upper respiratory tract may be underdiagnosed or misdiagnosed when resting endoscopic examination is performed. Dynamic endoscopy on a high-speed treadmill provides a far better true assessment and diagnosis of the dynamic obstructions of the upper equine respiratory tract. However, treadmill-exercising endoscopy is still only available in limited facilities that have the suitable equipment and personnel.

The availability of embarked endoscopes that could be used without a treadmill may make exercising endoscopy readily available to most equine practices. The development of the dynamic respiratory scope (DRS) has taken 2 yr of close collaboration between the engineers of a company manufacturing endoscopes and clinicians.

2. Materials and Methods
Equipment
DRS is a video-endoscopic system that features four parts: (1) a malleable insertion tube fixed to a purpose-made, non-traumatic bridle system, (2) a auto-lighting head tube that negates the need for a heavy and energy-consuming light source, (3) an integrated lavage system, and (4) control levers. The endoscope is connected to a 3-kg solid polyvinylchloride (PVC) box fixed onto the sulky or the rider. The video-endoscopic images are recorded continuously in a digital format onto a secure digital (SD) card, and they can be transmitted to a remote receiver up to 600 meters away. The PVC box contains all of the electronics as well as a supporting battery power source. The latter provides sufficient power for ≤45 min. The light intensity can be reduced during the equipment adjustment to save energy. The selected color temperature (4000–6000°K) provides high-quality images. The receiver for the tele-transmitted images contains a control screen for real-time visualization as well as a battery and a tripod. A remote control initiates the recording start and stop functions.

Animals
Over the 2 yr of development of the DRS, prototypes were tested on >20 normal cooperative horses that...
performed during trot, gallop, jumping, or endurance events.

From February to June 2008, 18 performance horses presented for investigation of abnormal respiratory noises at exercise and/or poor performance. These horses were subjected to exercising endoscopy without a treadmill in a medium-sized equine livery yard.

**Procedure**

Horses were prepared in three stages (Figs. 1–3).

1. The malleable insertion tube was inserted into the ventral meatus of one of the horse's nostrils.
2. The tube was attached to the purpose-made bridle system.
3. The battery processor source and the transmitting/recording device were fixed onto the sulky or the rider. Start and stop recording functions were controlled by the remote control hand piece. The video-endoscopic images were recorded onto the SD card for subsequent computer visualization. Real-time visualization was achieved by the receiver console either on the center of the training arena for saddle horses with riders or in a car following the horse on a parallel track for racehorses with sulkies (Fig. 4).

**3. Results**

All the examinations were performed with total safety for horses, drivers, riders, and equipment; 16
of 18 horses had a positive diagnosis of upper airway dynamic obstruction (Figs. 5–9). The type of performance and the diagnoses are shown in Table 1.

4. Discussion

Preliminary results established the safety and reliability of the system. High-quality images were achieved directly on site. The number of horses examined was limited mainly for two reasons. First, the work involved only a moderately sized yard. Second, dynamic endoscopy was largely unknown in the region, because no facility had existed previously. The clinicians had to explain and convince the owners that exercising endoscopy was necessary to identify the origin of abnormal respiratory noises.
The number of trotters examined was greater
than the number of gallopers, but this was consis-
tent with the breed proportion of the clientele.
The main interest for the practitioners involved in
this study was the sudden “appearance” of upper
respiratory dynamic obstructions among their horse
population. Previously, they were unable to cor-
rectly diagnose these diseases. They found the sys-
tem easy to perform on any type of horses and
during any type of performance. Moreover, they
were able to perform the examination at low cost
(compared with a treadmill endoscopy) and repeat-
edly from one day to another without delay and
transportation to a treadmill center. The tech-
nique also seemed safer, because it avoided the spe-
cific risks inherent to the treadmill (e.g., the horse
falling or jumping out).

The malleable rigid tube provided more stable
video images than classical treadmill endoscopy.
The equipment has subsequently been tested on the
treadmill by other clinicians. The more stable im-
ages and the usefulness of the equipment improved
the quality of the interpretation significantly.

Some problems were encountered during both the
development period and the preliminary trial. A num-
er of key practical points may help the clini-
cian avoid these disagreements when starting to use
the equipment.

- The preparation of the horse should be opti-
mal, because it may be difficult to readjust or
reposition the system after the exercise has
started, especially on racehorses.
- A prior resting endoscopy is necessary not only
for detecting any abnormality at rest but also
for evaluating horse compliance/cooperation.
- Mounted endoscopy (gallopers and saddle
horses) should be performed with an experi-
enced rider, because any fall may be dangerous
for the equipped rider and for the equipment.
- Examinations should not be performed during
rain, because the system is not watertight.
- The battery should be fully charged before the
examination to avoid loss of video records. The
battery can last 45 min at full light power. This
allows two successive examinations on trot-
ters, but sometimes only one examination on
gallopers is possible. Battery charging time
is 2 h. Additional batteries may be needed if
several examinations are run sequentially.
  - The lens is rinsed with a mercorobutol solution
before the tube insertion to avoid secretions
adherence because the lens lavage cannot be
performed during exercise. This is of partic-
ular importance with racehorses.
  - The noseband should be carefully tightened,
because it is a “fix” point.
  - Tube excess should be guided onto the horse’s
neck to avoid floating.
  - The PVC box should be fixed with the designed
attachment system. This is especially impor-
tant on sulkies where a perfect stability should
be ensured before starting the examination.
  - Head movements should be controlled and lim-
ited, especially in large horses, to avoid
wrenching the tube from the PVC box or dis-
placing/extracting the tube from the nasophary-
ynx.

Some recommendations have been made to the man-
ufacturer to improve the usefulness of the equip-
ment. The following modifications are available.

- An automatic water pump pulsing at 30-s
intervals.
- A new harness for PVC-box positioning on the
rider’s back.
- A new aluminum plaque for better fixation
onto the sulky.
- A water tight bag for convenience and PVC box
protection during rain.

5. Conclusion
In addition to the usefulness and the reduced cost of
the examination, it is expected that some abnormal-
ities that occur only in natural conditions, such as
the impact of the training system, the ground qual-
ity, the rider’s weight, the sulky’s weight, and the
